

Data analysis of recordings of slow earthquakes: Tectonic tremor, low-frequency earthquakes and slow slip events

Ariane Ducellier

University of Washington

General Exam - October 25th 2019

Introduction

1 Introduction

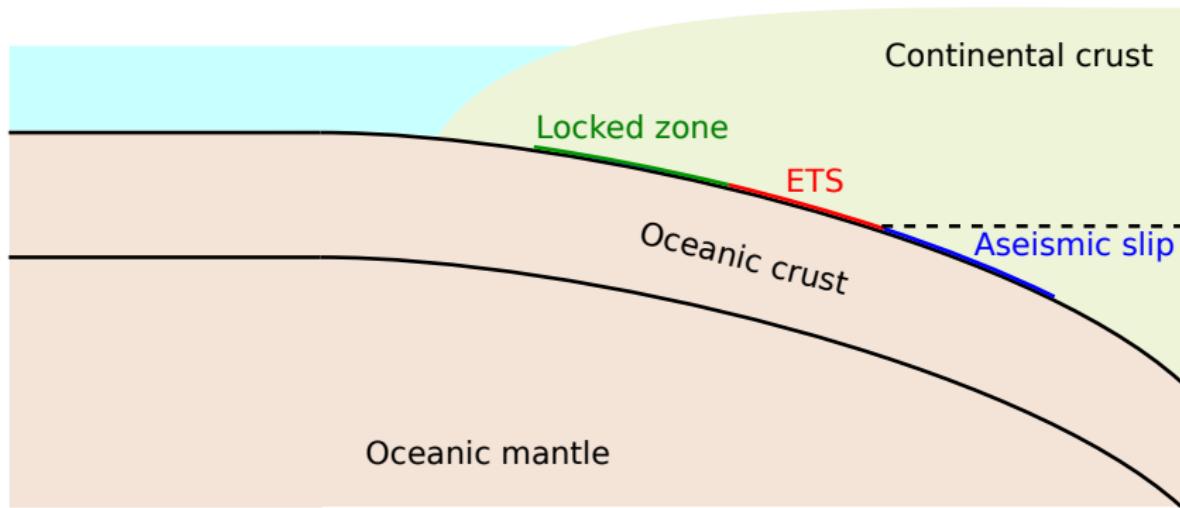

- Slow slip
- Tectonic tremor
- Low-frequency earthquakes (LFE)
- Episodic Tremor and Slip (ETS)
- Research questions

2 Depth of the source of the tectonic tremor

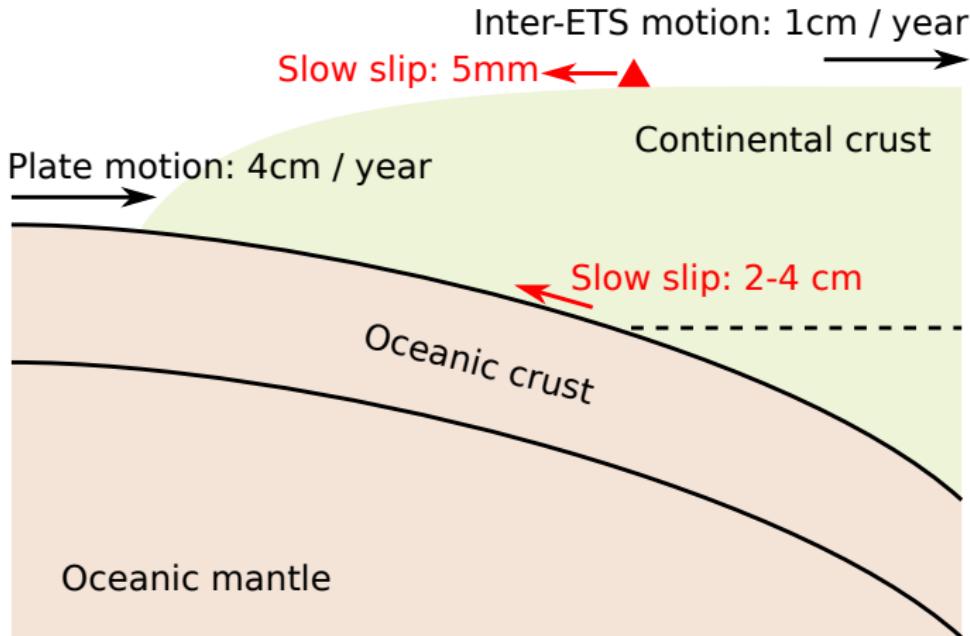

3 A low-frequency earthquakes catalog for southern Cascadia

4 Detection of slow slip events in New Zealand

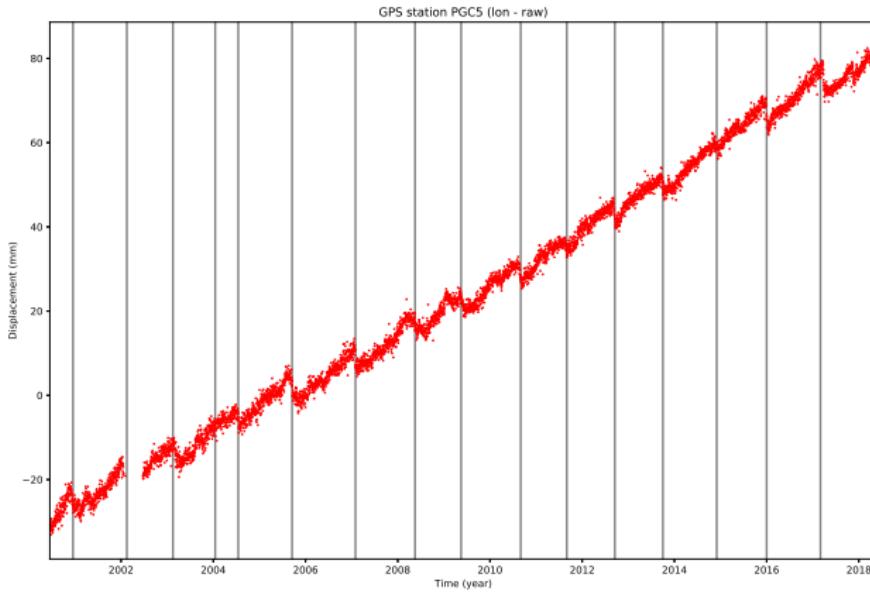

Slow earthquakes

Slow slip

Slow slip

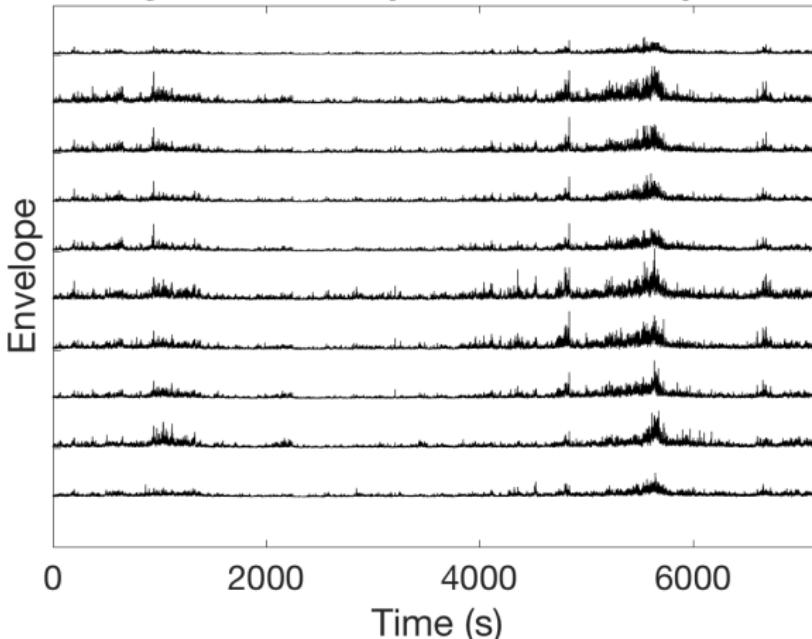

Tectonic tremor

- Long (several seconds to many minutes)
- Low amplitude
- Emergent onsets
- Absence of clear impulsive phases

Tectonic tremor

Array BH - Envelope of North component

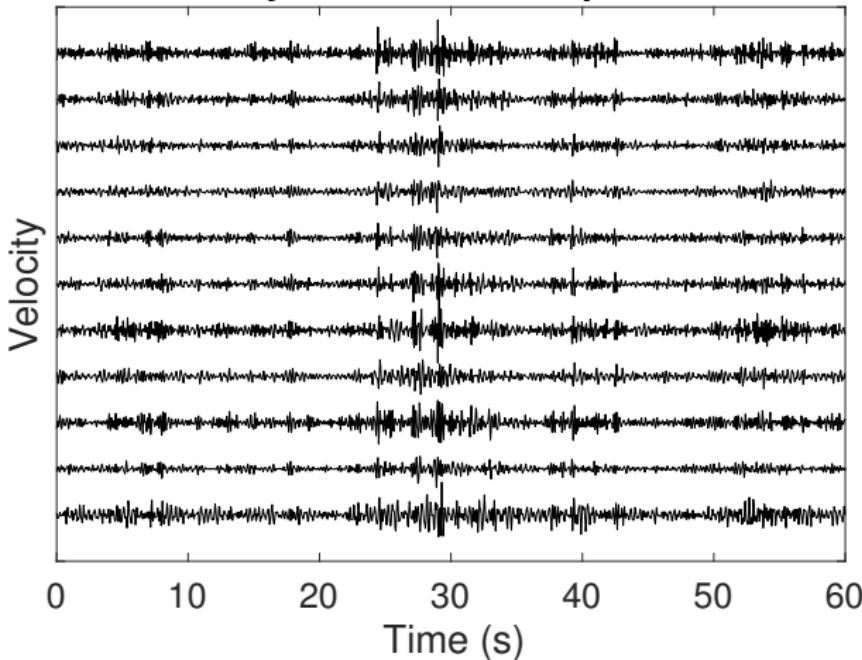

Low-frequency earthquakes (LFE)

- Small magnitude earthquakes ($M \sim 1$)
- Frequency content (1-10 Hz) lower than for ordinary earthquakes (up to 20 Hz)
- Source located on the plate boundary,
- Focal mechanism: Shear slip on a low-angle thrust fault dipping in the same direction as the plate interface

Low-frequency earthquakes (LFEs)

Array DR - North component

Episodic Tremor and Slip (ETS)

- Tectonic tremor observations spatially and temporally correlated with slow slip observations (Nankai, Cascadia)
- Only biggest tremor episode associated with slow slip
- No spatial or temporal correlation in other regions like New Zealand

Depth of the source of the tectonic tremor in the eastern Olympic Peninsula

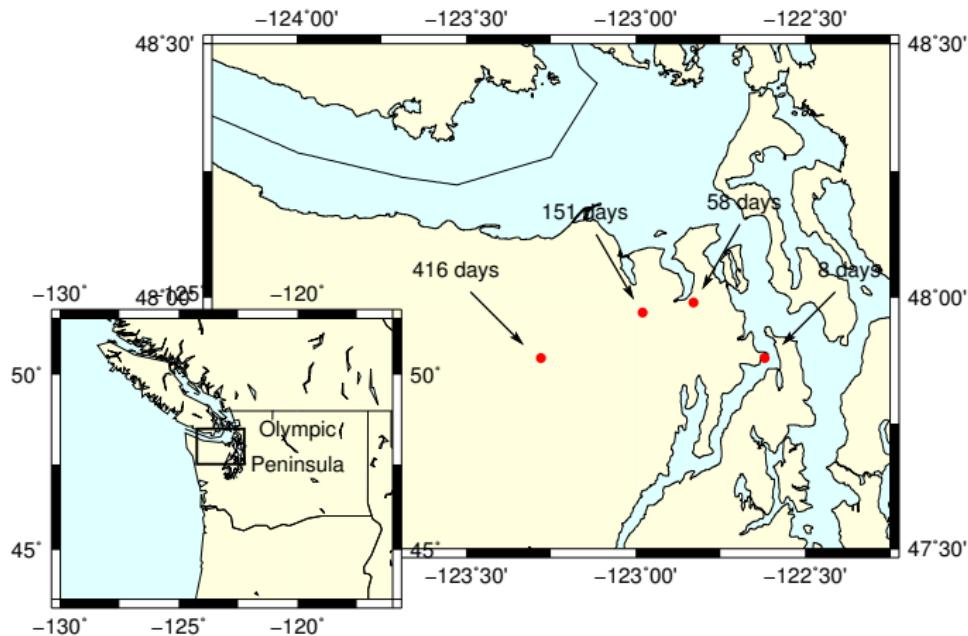

- Lack of impulsive phases → Difficult to determine the depth of the source of the tremor
- Tectonic tremor is at least partly made of a swarm of LFEs
- LFEs are located on the plate boundary

→ Research question: Is the source of the tectonic tremor located on the plate boundary? What is the depth extent of the location of the source of the tremor?

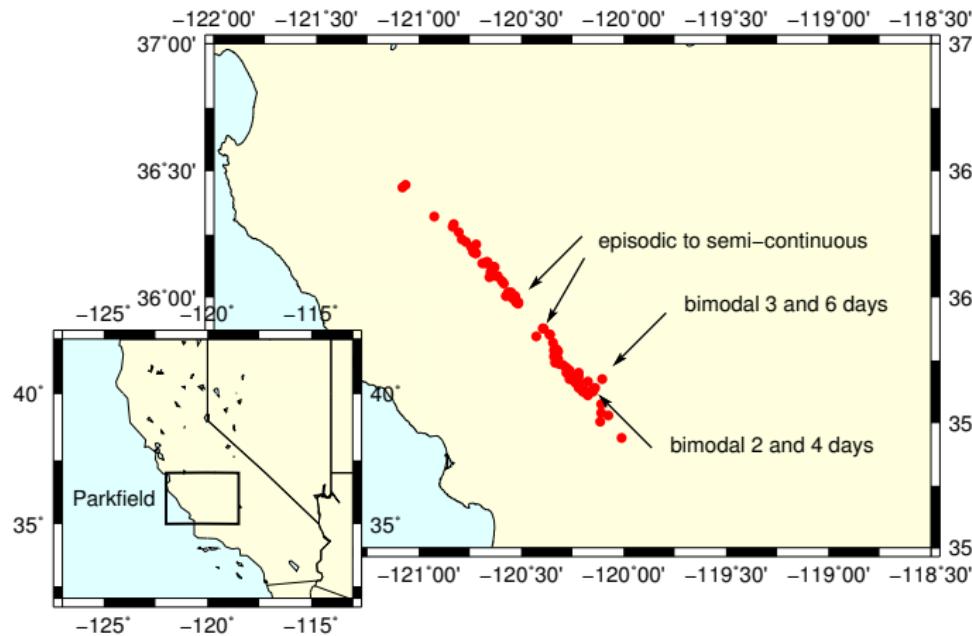

A low-frequency earthquake catalog for southern Cascadia

- LFE grouped into families of events
- All the earthquakes of a given family originate from the same small patch on the plate interface
- LFE recur more or less episodically in a bursty manner
- Wide range of recurrence behavior between seismic regions, and within the same seismic region

LFE in Washington State

LFE on the San Andreas Fault

A low-frequency earthquakes catalog for southern Cascadia

- LFE families in southern Cascadia:
 - 34 LFE families on the subduction zone
 - 3 LFE families on two strike-slip faults from the San Andreas Fault system
- Wide range of recurrence behavior between Washington State and the San Andreas Fault, and within the San Andreas Fault zone

→ Do low-frequency earthquakes families behave similarly or differently in southern Cascadia, compared to Washington State and the San Andreas Fault?

Detection of slow slip events in New Zealand

- Small ($M \sim 5$) or long (several months) slow slip events are harder to detect
- In Cascadia, Mexico, tremor used as a proxy to study slow slip events
- Different pattern in northern New Zealand:
 - Tremor source located downdip of the slow slip on the plate boundary
 - Tremor activity does not seem to increase during slow slip events

→ Can we detect smaller and / or longer slow slip events in the absence of spatially and temporally correlated tectonic tremor?

Depth of the source of the tectonic tremor

1 Introduction

2 Depth of the source of the tectonic tremor

- Motivation
- Data
- Method
- Results
- Discussion and Conclusion

3 A low-frequency earthquakes catalog for southern Cascadia

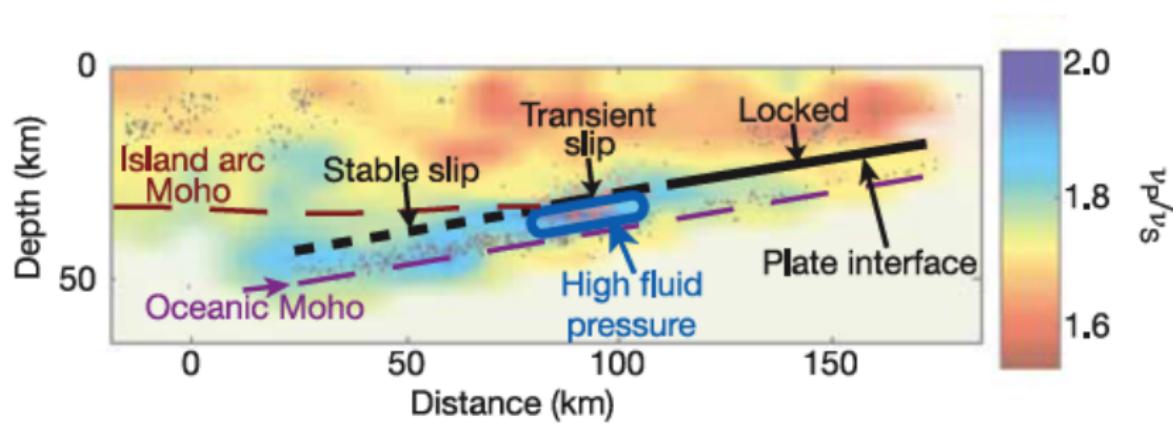

4 Detection of slow slip events in New Zealand

Tremor and LFEs

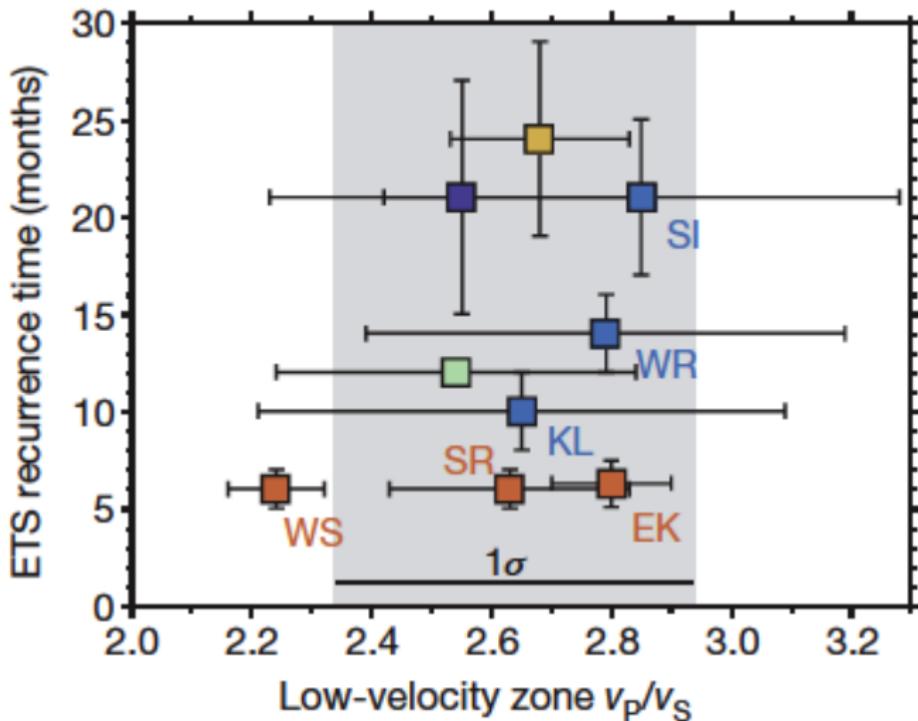

- Tremor can be explained as a swarm of LFEs
- LFE occur as shear faulting on the subduction-zone plate interface

Shelly et al. (2007), Ide et al. (2007)

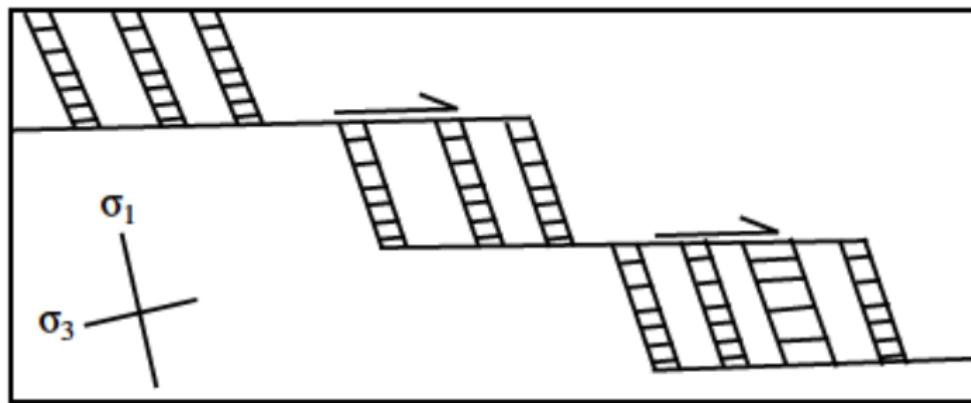

High pore fluid pressure in the oceanic crust

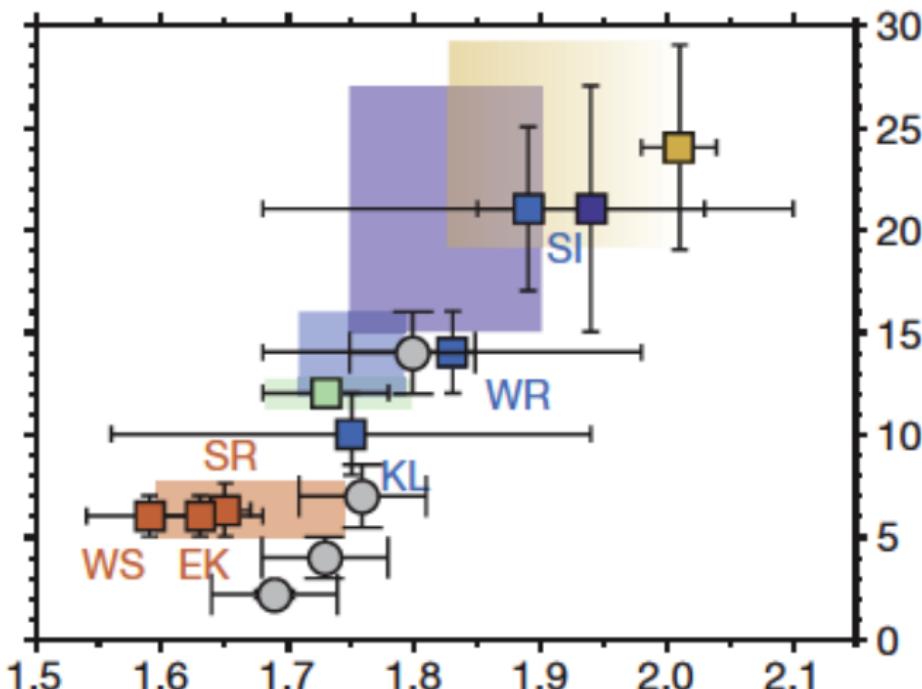

High pore fluid pressure in the oceanic crust

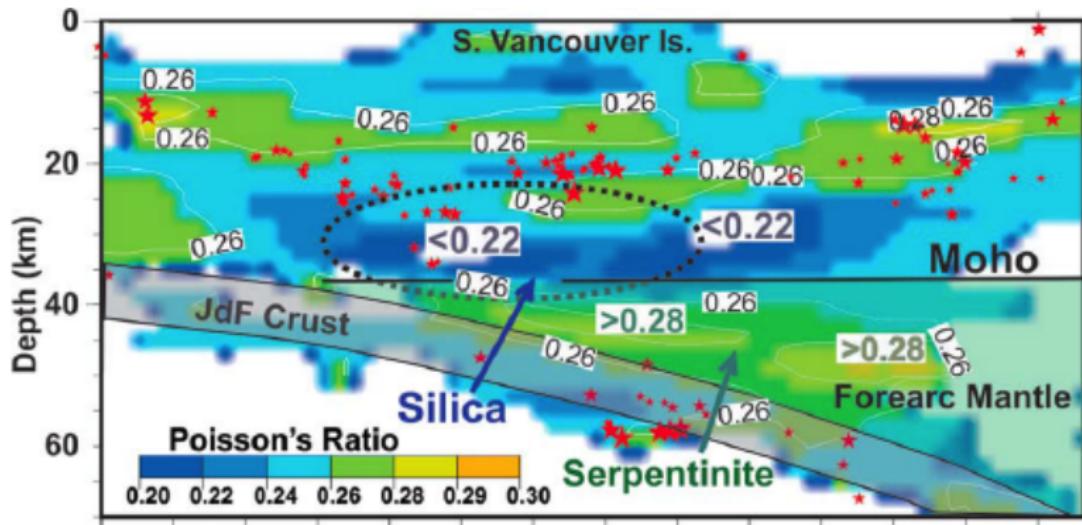

Fracture network

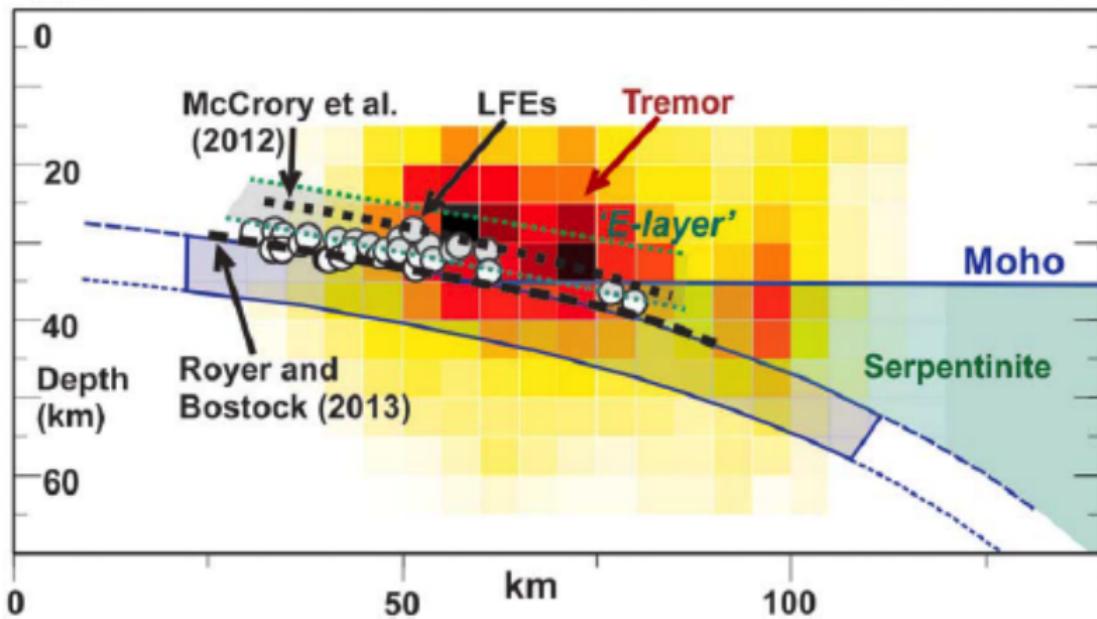

Low V_P/V_S ratio in subduction zones

Low V_P/V_S ratio in the overriding plate

Inferred location of the source of the tremor

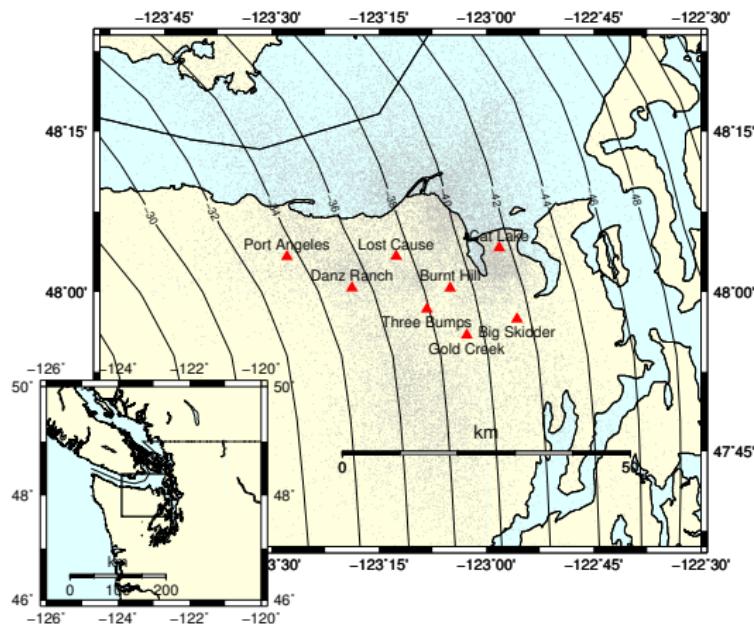

Where is the source of the tremor located?

- Same location as LFEs → Very thin layer at the plate boundary
- Same location as quartz → Thick layer above the plate boundary, in the continental crust

→ How to constrain better the location of the source of the tremor?

Cascadia Array of Arrays

- Cascadia Array of Arrays experiment (2009-2010)
- Eight arrays of seismic stations in the Olympic Peninsula
- Recorded the main ETS event in August 2010, and the 2011 ETS event
- Tremor located just under the arrays

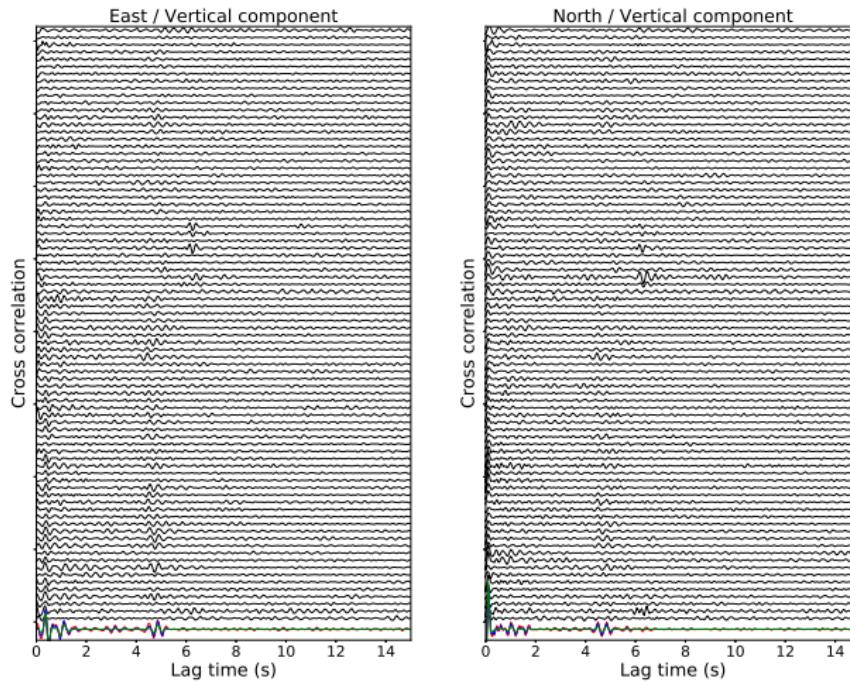

Tremor catalog

- 28902 one-minute-long time windows where tectonic tremor is recorded
- For each tremor window: Beginning time, latitude, longitude, and depth of the tremor source
- Start date: June 20th 2009
- End date: September 30th 2010

Stacking of tremor recordings

- Tectonic tremor recorded at the Big Skidder array and which source is located in a 5x5 km cell just under the array
- 70 one-minute-second-long time windows
- For each time window:
 - For each station, cross-correlate the horizontal component with the vertical component
 - Stack (linearly) the cross-correlation over all the stations of the array
- Plot all the 70 stacked cross-correlation
- Stack the 70 signals with a linear, power, or phase-weighted stack

Stacking of tremor recordings

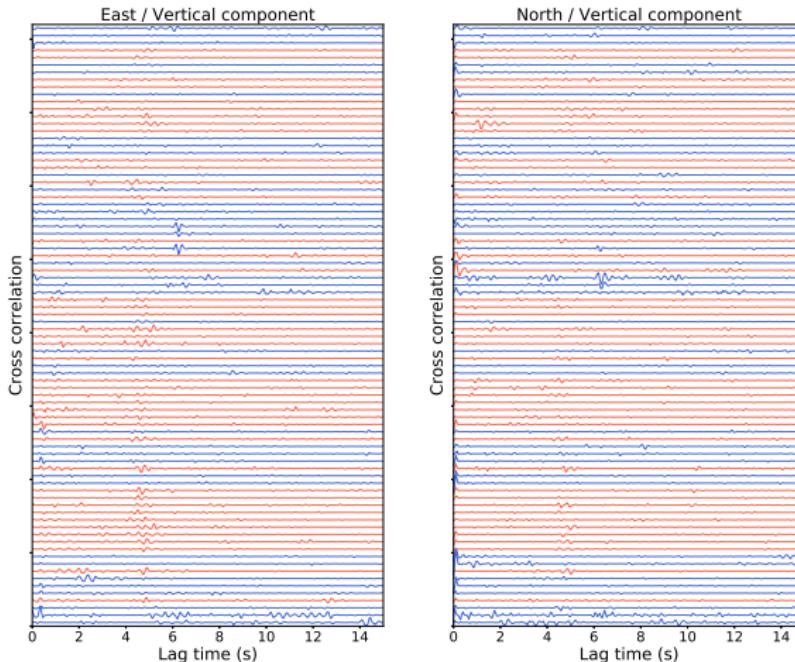

Clustering of cross correlation functions

Does the cross-correlation for a given one-minute-long time windows look like the stack over all time windows?

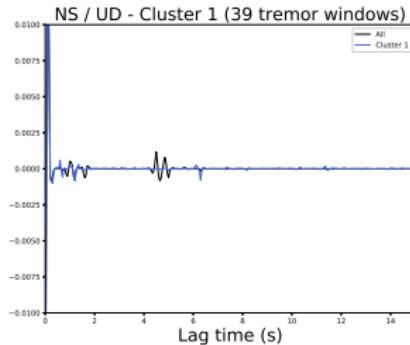

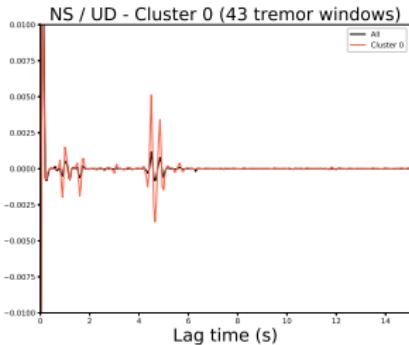

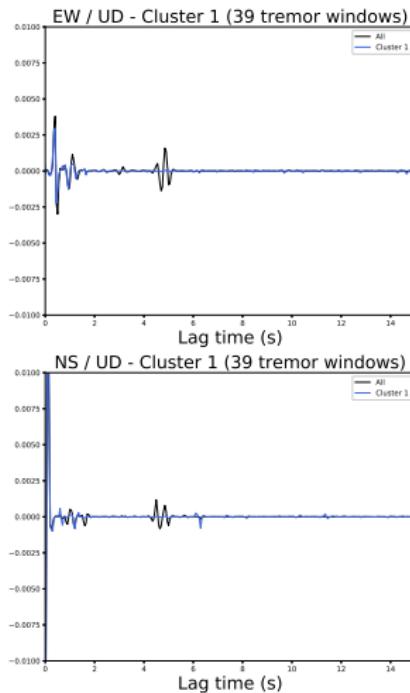

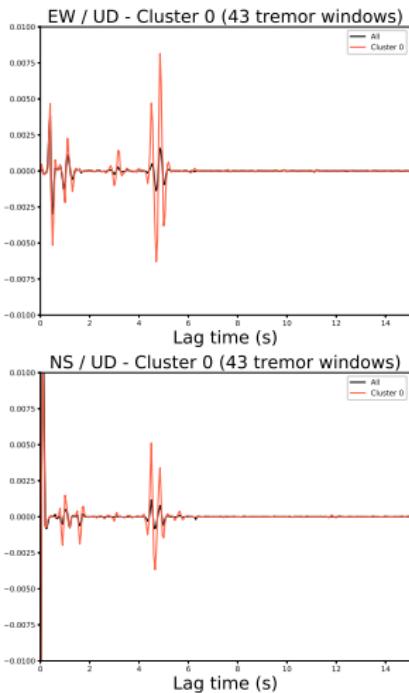

- Ratio RMS between 4 and 6 s / RMS between 12 and 14 s
- Cross-correlation between one cross-correlation and the stack:
 - Maximum cross-correlation value
 - Cross-correlation at time lag 0
 - Time lag corresponding to the maximum cross-correlation value

→ K-means clustering → Two clusters (good time windows / bad time windows)

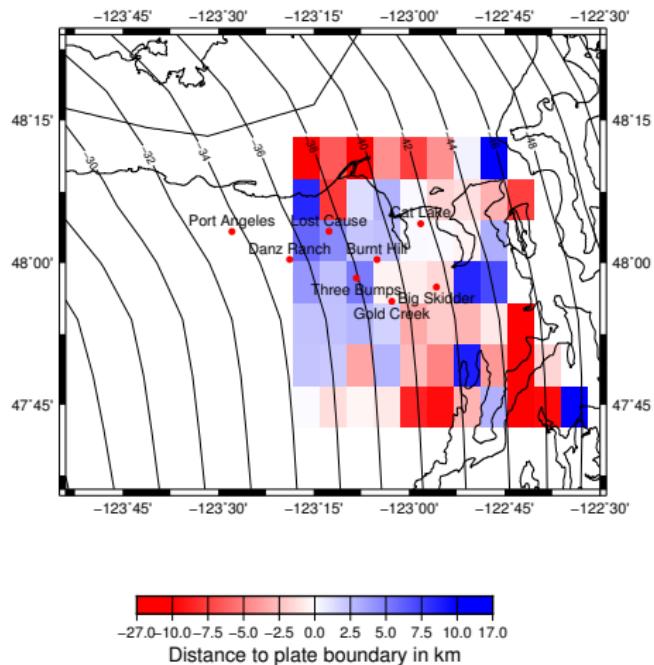

Clustering of cross correlation functions

Stacked cross correlation

Distance to plate boundary

Interpolation

- Number of tremor
- ratio peak cc / RMS
- Distance to array (strike / dip)

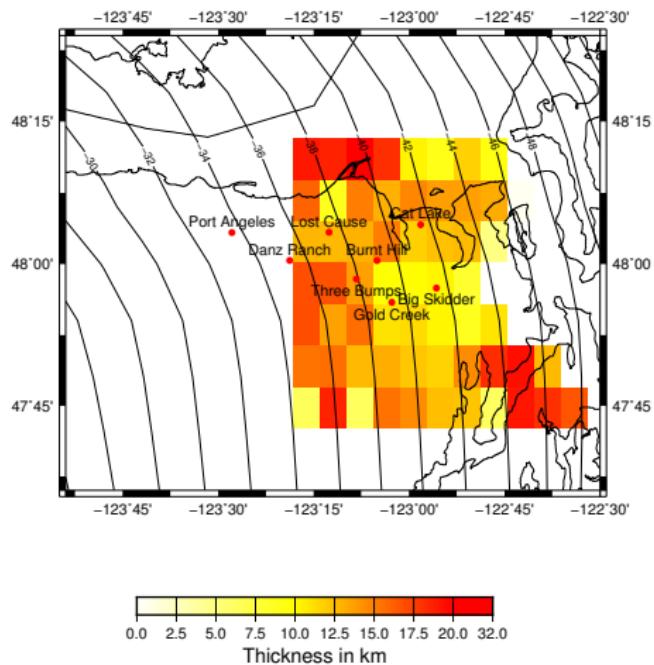

→ Weights for interpolation of results from 8 arrays

Distance to plate boundary

Distribution of time lags

Width of the distribution

Thickness of the tremor zone

Conclusion

A low-frequency earthquakes catalog for southern Cascadia

1 Introduction

2 Depth of the source of the tectonic tremor

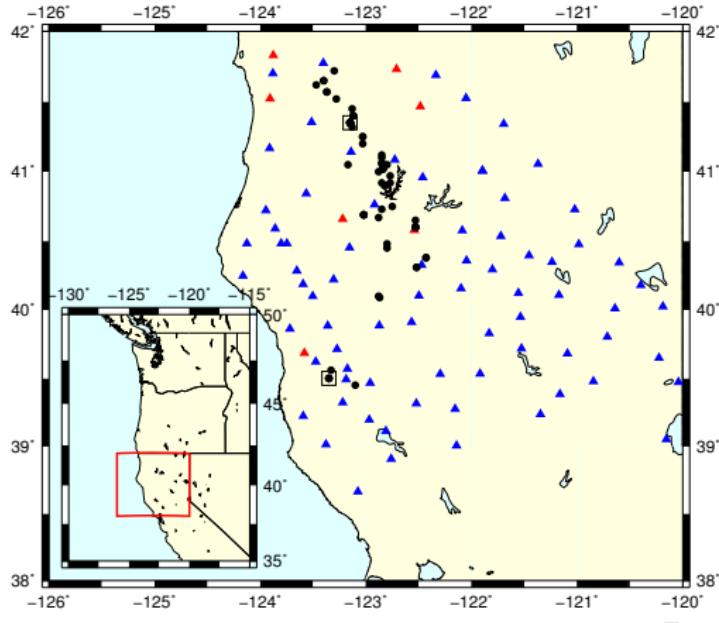

3 A low-frequency earthquakes catalog for southern Cascadia

- Extension of an LFE catalog for southern Cascadia
- Effect of nearby earthquakes on LFE activity
- Characterization of LFE clustering
- Temporal model of LFE occurrence rate

4 Detection of slow slip events in New Zealand

5 Time line

Current catalog

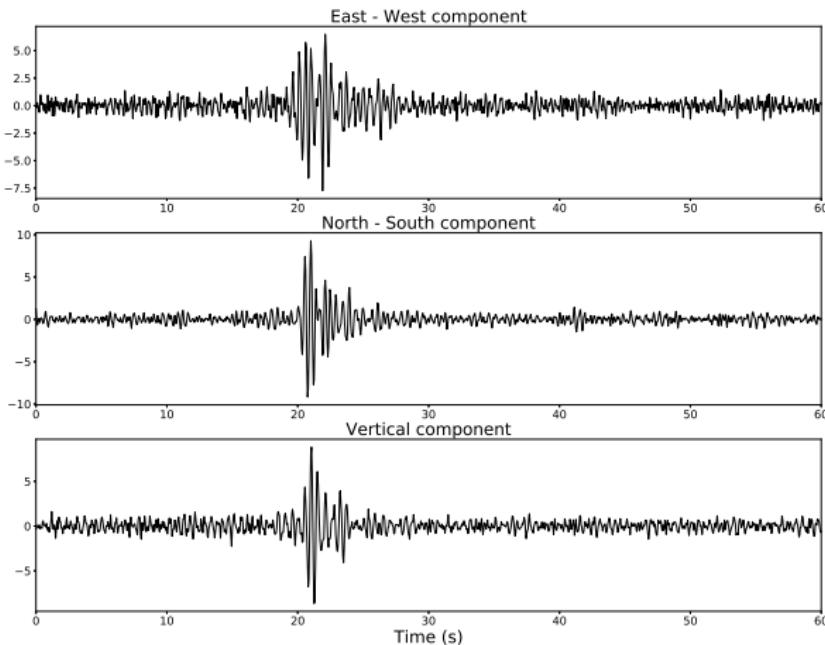

Current catalog

- Subduction zone families
 - 34 families
 - Period covered: April 2008
 - One burst of LFE lasting a few days and propagating from south to north
- Strike-slip fault families
 - 3 families
 - Period covered: March and April 2008
 - Active all the time, several bursts of LFE

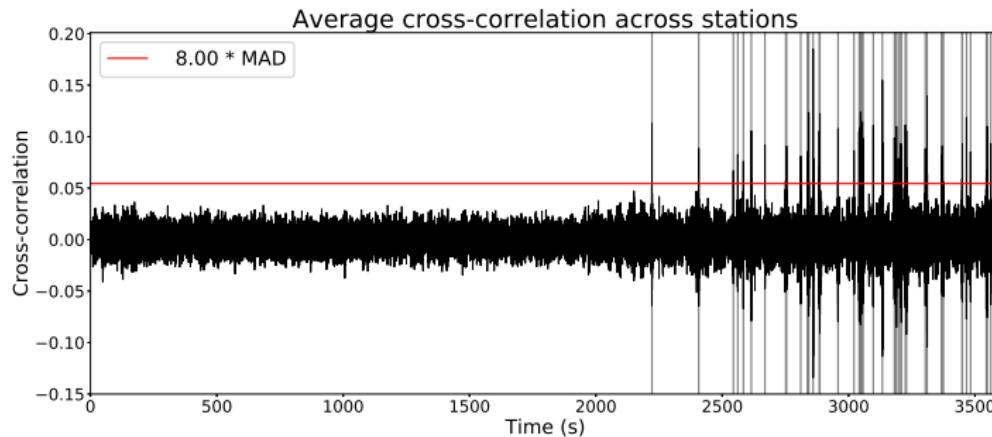

Creating templates

Templates for permanent station KRMB

Finding new LFE

Analysis of one hour of seismic data

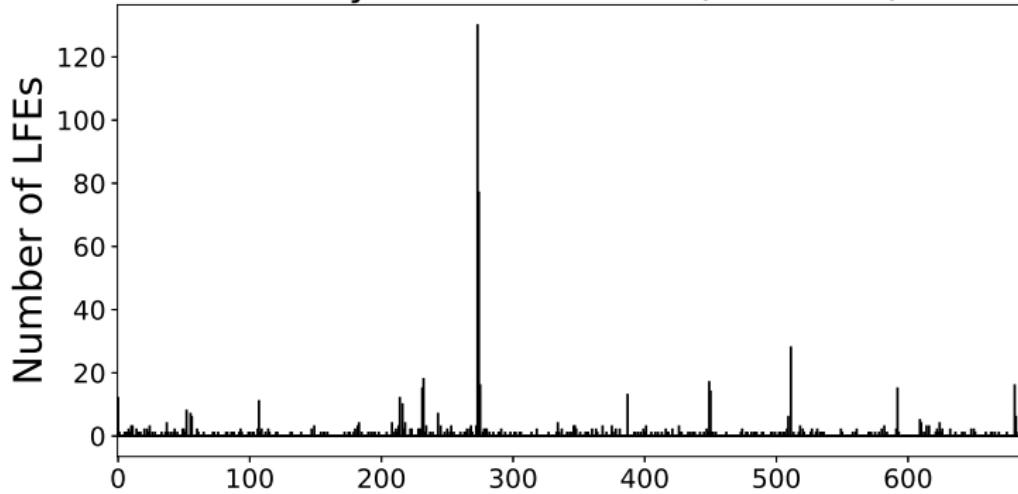

Comparison with existing catalog

Family 080421.14.048

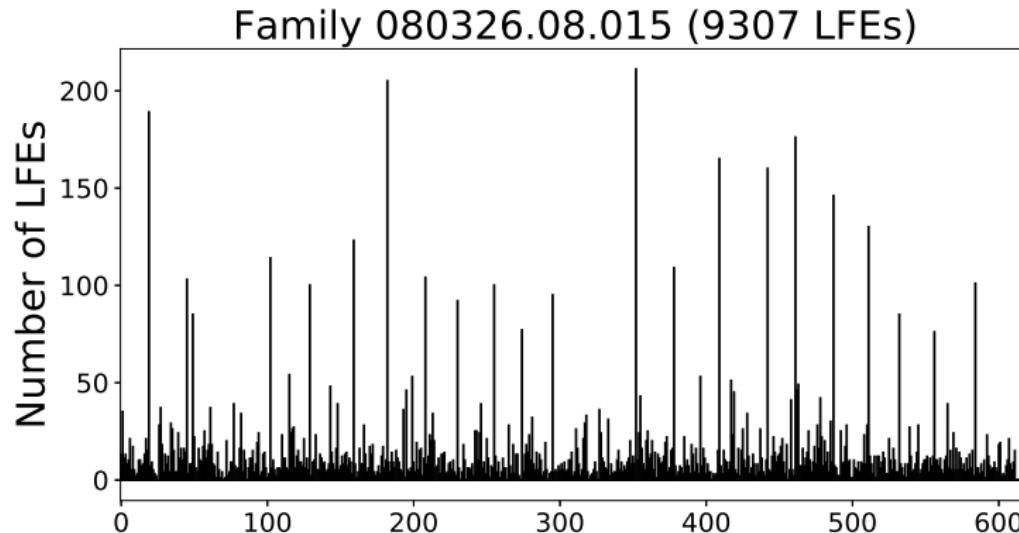

Number of LFE in my catalog	236
Number of LFE in the catalog by Plourde <i>et al.</i>	225
Number of LFE added in my catalog	13
Number of LFE missing in my catalog	2
Number of LFE present in both catalogs	223

Extension of the catalog

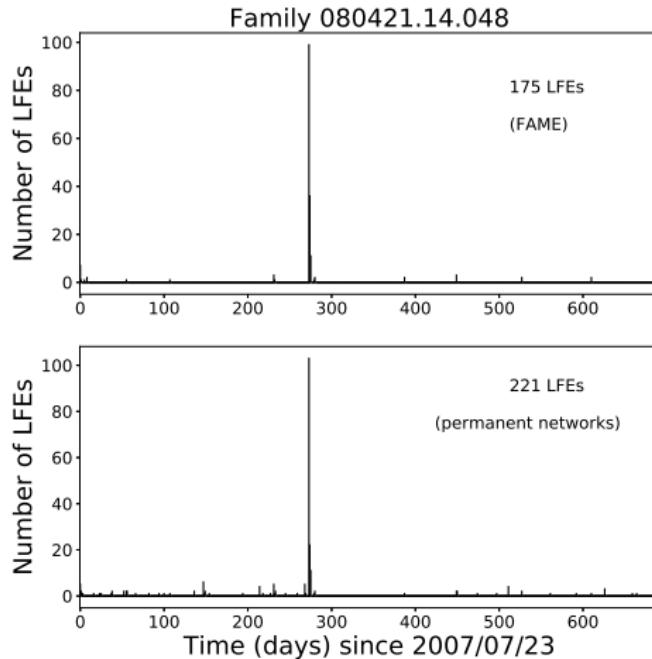

Family 080421.14.048 (821 LFEs)

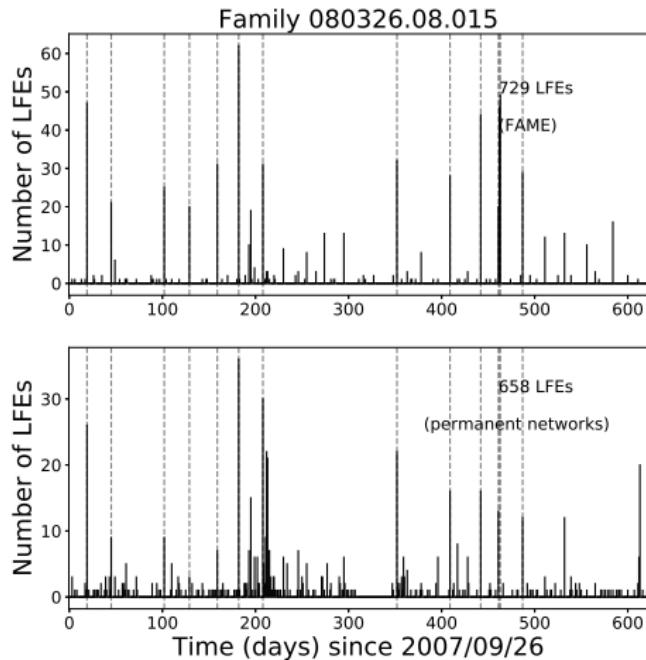

Extension of the catalog

Detection of LFE with permanent networks

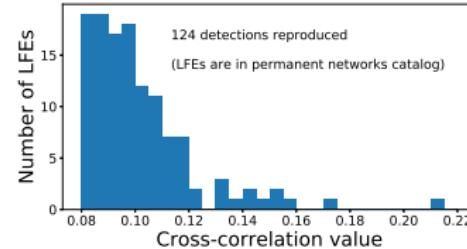

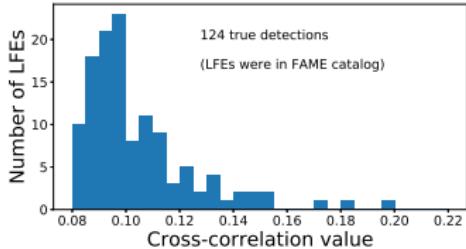

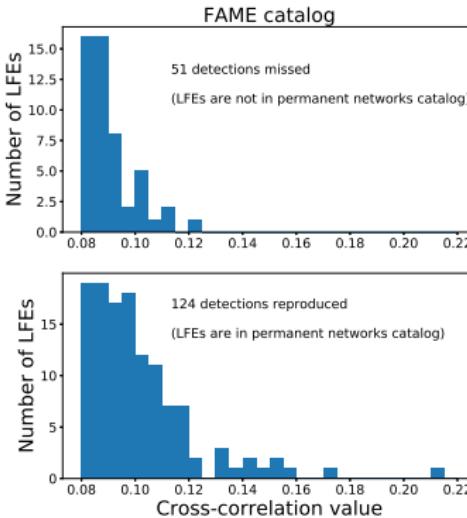

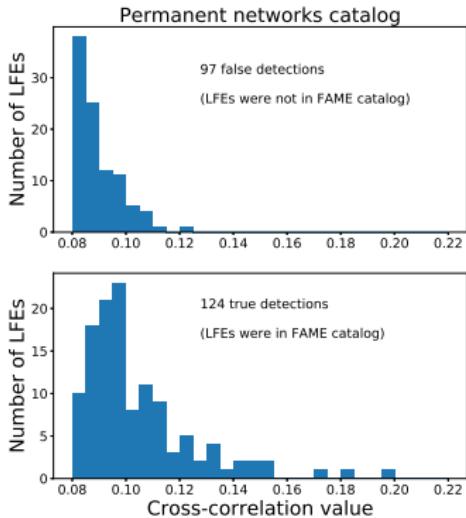

Detection of LFE with permanent networks

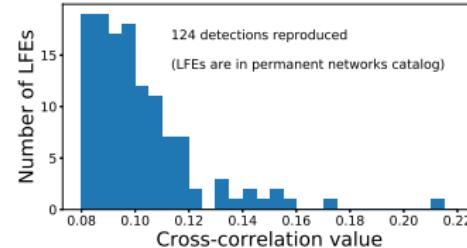

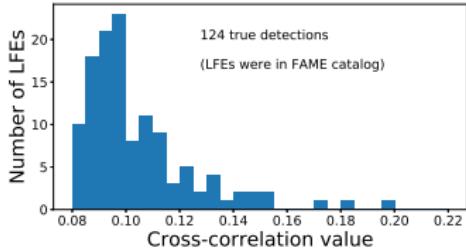

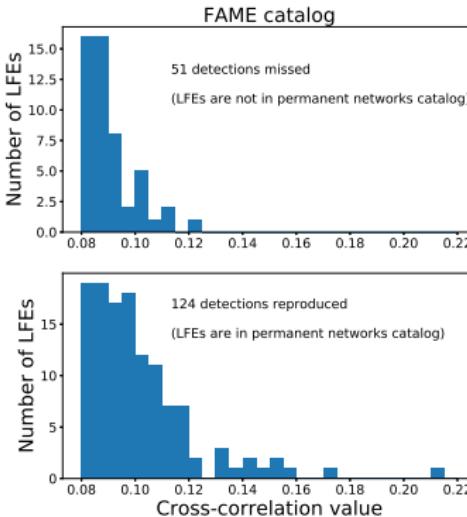

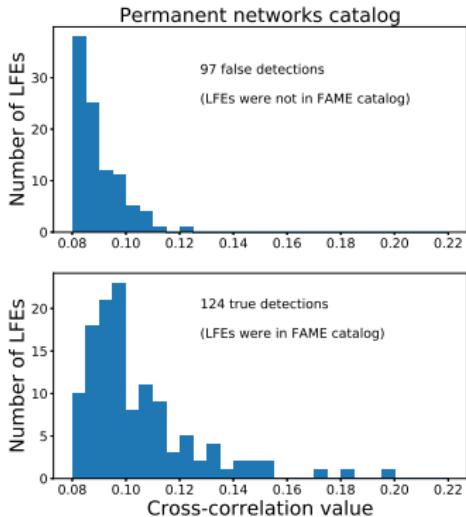

Comparison FAME - permanent networks

Family 080421.14.048

Comparison FAME - permanent networks

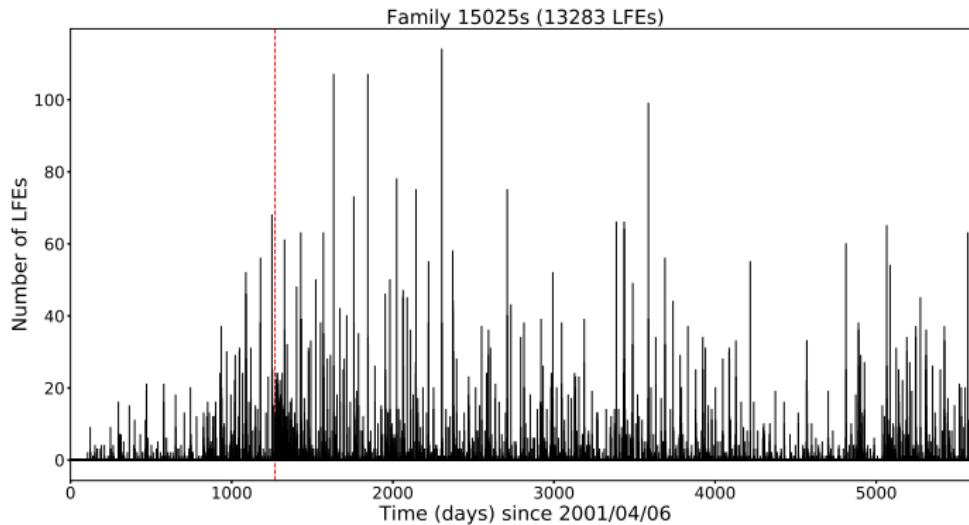

Family 080421.14.048

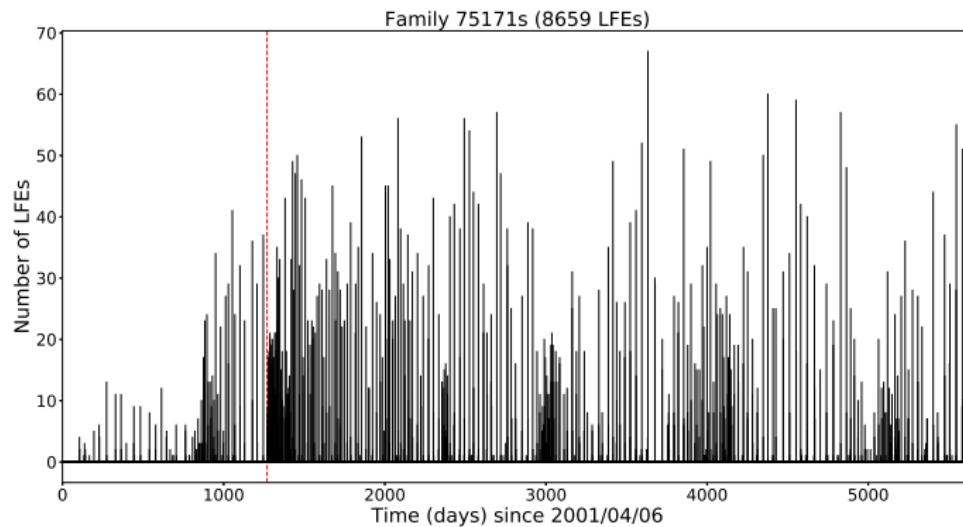

Future work

- Two-year-long catalog for all LFE families
- Computation of new templates for the permanent networks
- Whenever possible, extension of the LFE catalog to 2009-2019

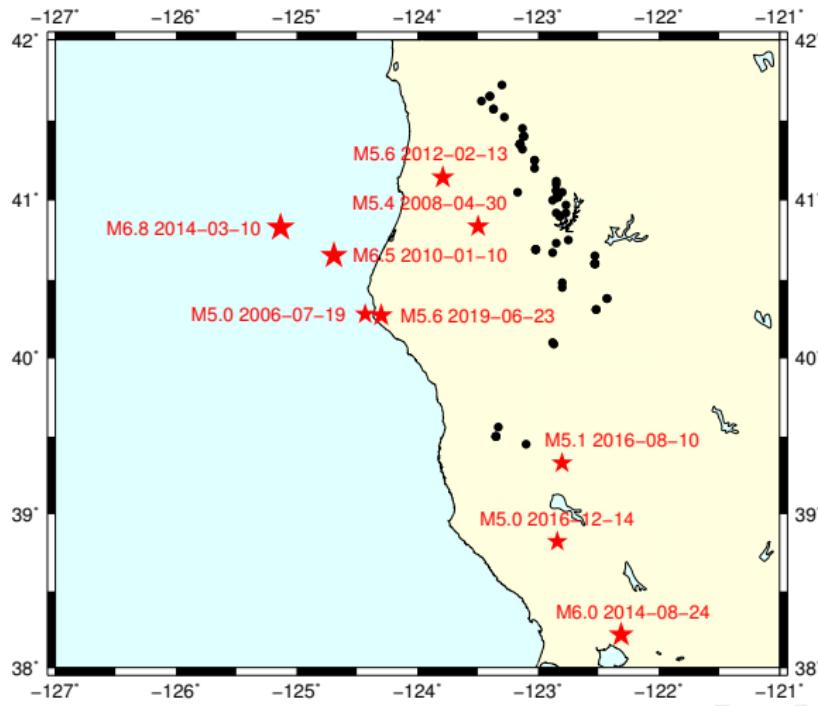

Effect of the 28 September 2004 M6.0 Parkfield earthquake

Effect of the 28 September 2004 M6.0 Parkfield earthquake

Moderate earthquakes in southern Cascadia

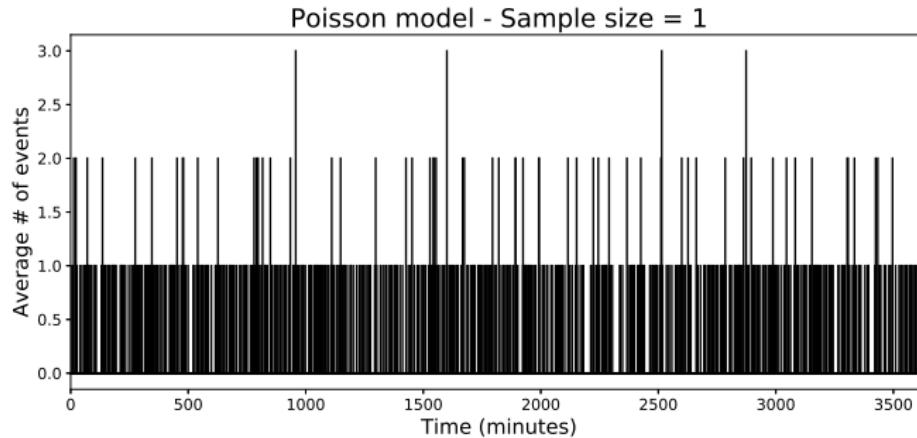

Future work

- Event rate before the earthquake
- Event rate after the earthquake
- Comparison between two event rates: Computation of likelihood ratio

Long-range dependence

- Relates to the slow rate of decay of the statistical dependence between two points with increasing time interval between the points
- The fractional index d represents how fast the variance in the number of LFEs in a time window of a given length increases with the length of the time window considered
- $0 < d < 0.5$ is characteristic of long-range dependence

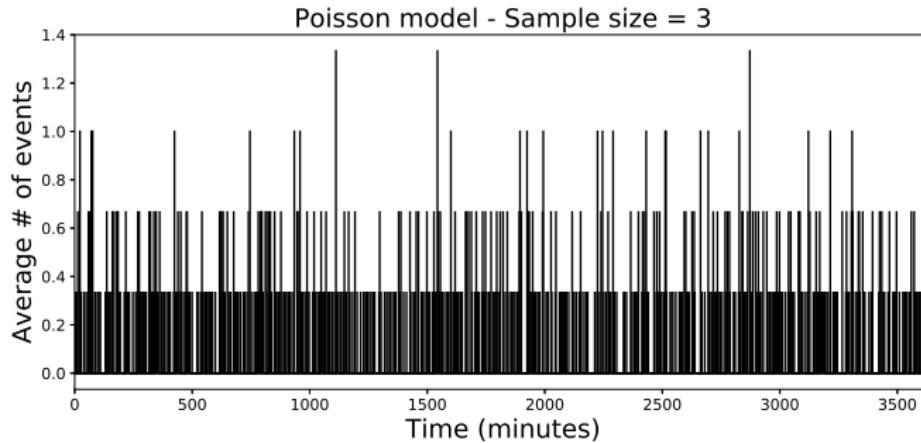

Homogeneous Poisson process

Number of events recorded during one day

→ Variance over 3645 values = 0.206

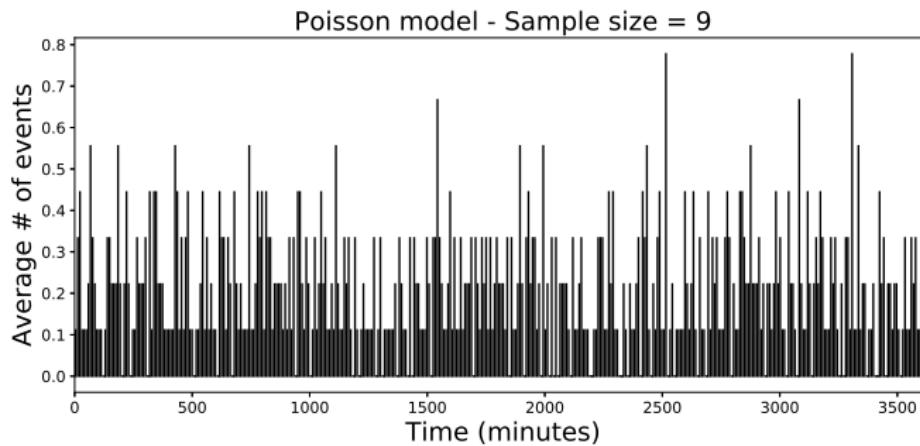

Homogeneous Poisson process

Number of events recorded during 3 days

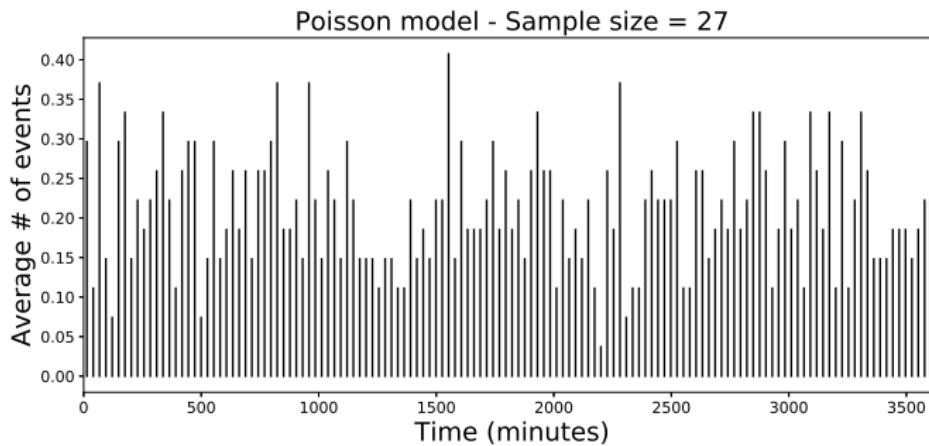

→ Variance over 1215 values = $6.62 \cdot 10^{-2}$

Homogeneous Poisson process

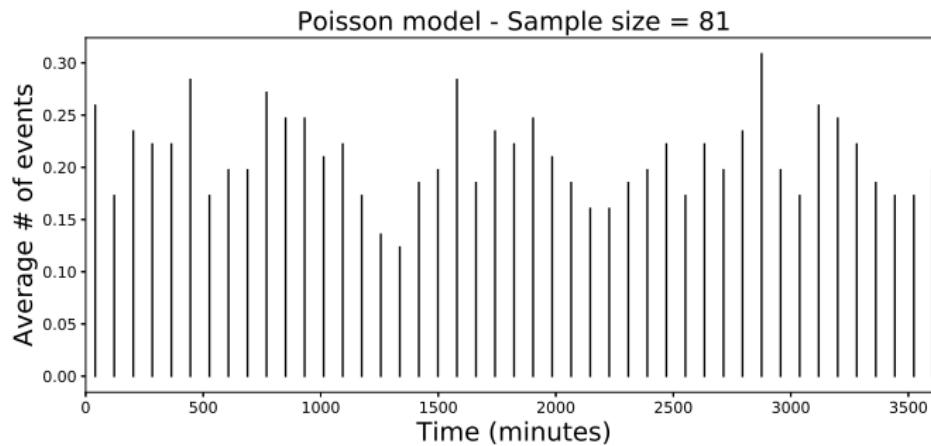

Number of events recorded during 9 days
 → Variance over 405 values = $2.14 \cdot 10^{-2}$

Homogeneous Poisson process

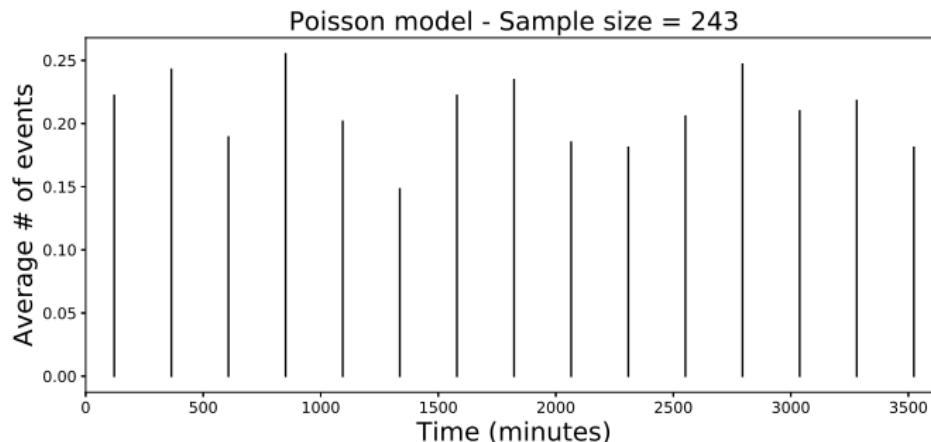

Number of events recorded during 27 days
 → Variance over 135 values = $5.56 \cdot 10^{-3}$

Homogeneous Poisson process

Number of events recorded during 81 days
→ Variance over 45 values = $1.54 \cdot 10^{-3}$

Homogeneous Poisson process

Number of events recorded during 243 days
 → Variance over 15 values = $8.05 \cdot 10^{-4}$

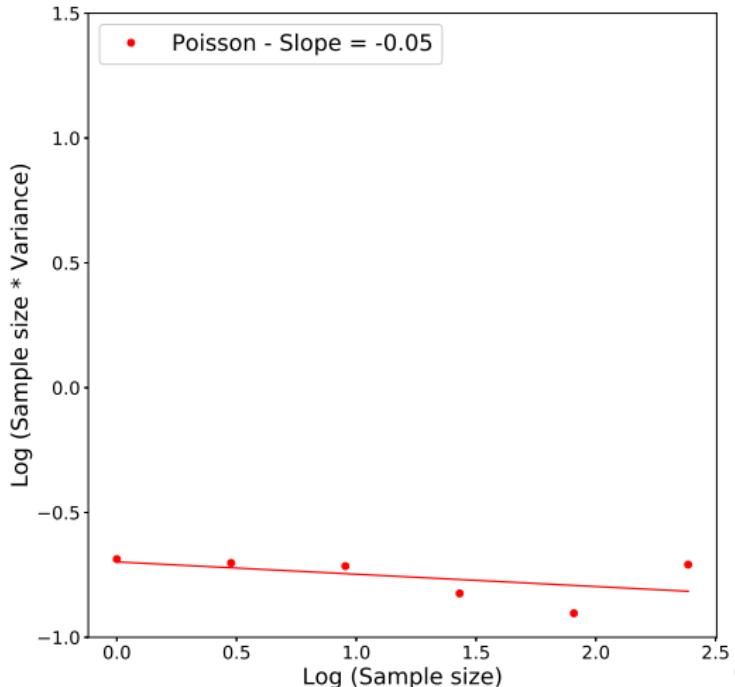

Variance vs Length of time window

$V = \text{Variance}$

$m = \text{Sample size}$

V behaves as m^{2d-1}

$\rightarrow d = 0$

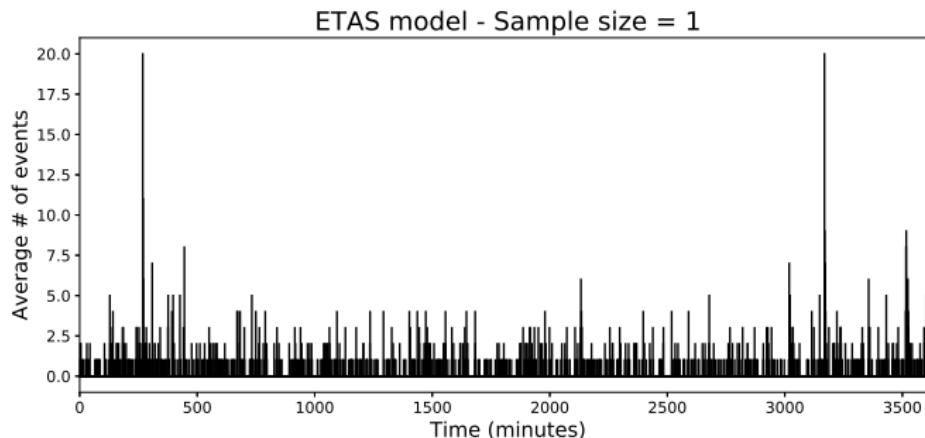

ETAS model

Epidemic-Type Aftershock Sequence (ETAS) model:

- Magnitude frequency distribution law of Gutenberg and Richter
- Omori-Utsu law of aftershock decay
- Each event, irrespective of whether it is a small or a big event, can trigger its own offspring

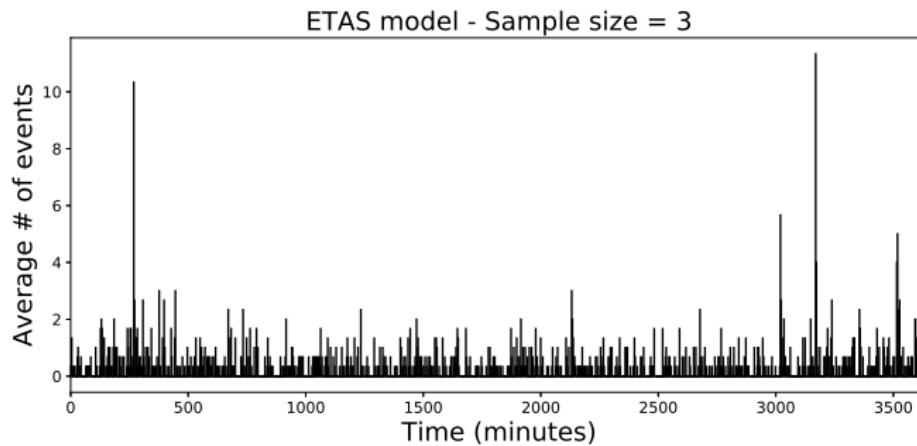

$$\lambda = \mu + A \sum_{t_i < t} e^{\alpha(M_i - M_0)} \left(1 + \frac{t - t_i}{c}\right)^{-\rho} \quad (1)$$

ETAS model

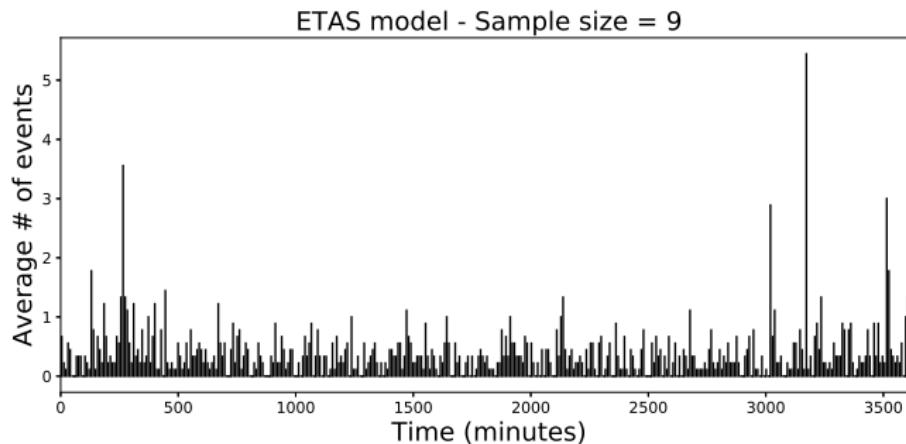

Number of events recorded during one day
→ Variance over 3645 values = 0.9636

ETAS model

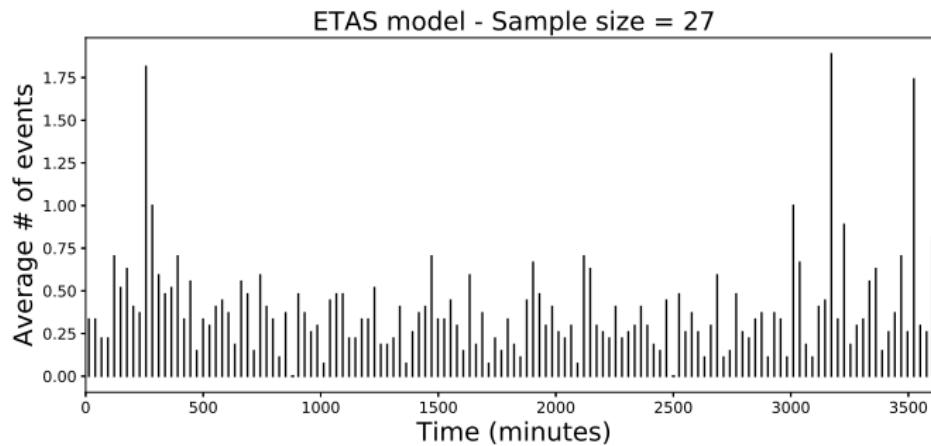

Number of events recorded during 3 days
→ Variance over 1215 values = 0.494

ETAS model

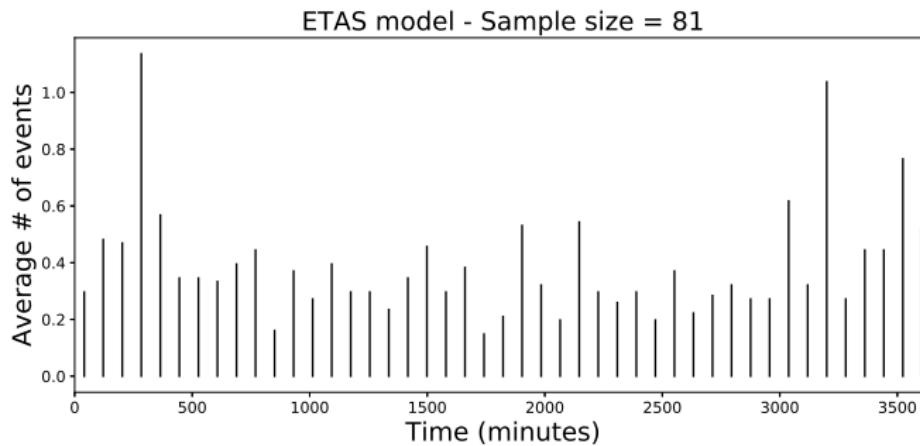

Number of events recorded during 9 days
→ Variance over 405 values = 0.220

ETAS model

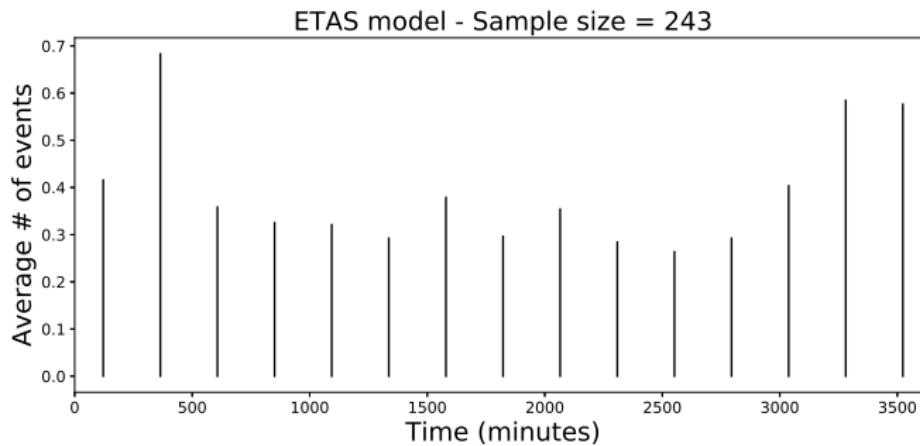

Number of events recorded during 27 days
→ Variance over 135 values = 0.0822

ETAS model

Number of events recorded during 81 days
→ Variance over 45 values = 0.0381

ETAS model

Number of events recorded during 243 days
→ Variance over 15 values = 0.0151

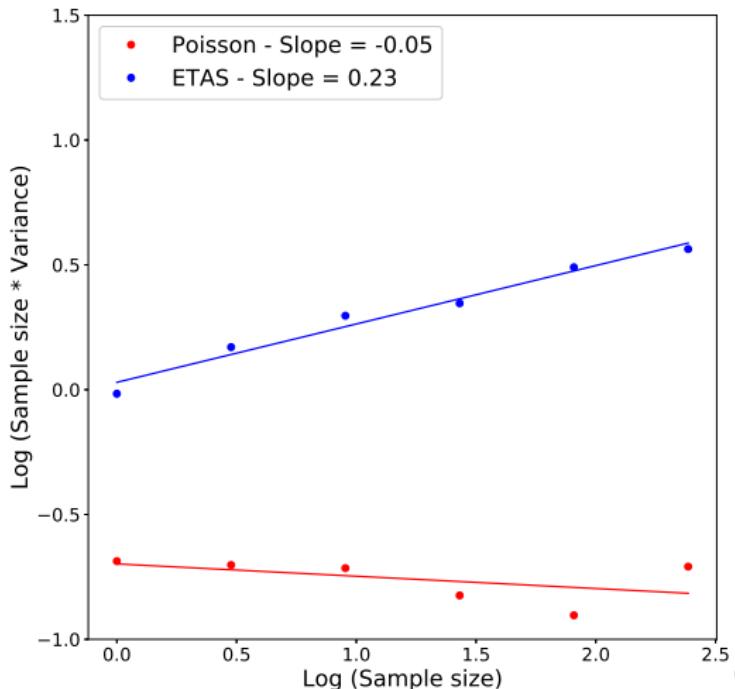

Variance vs Length of time window

$V = \text{Variance}$

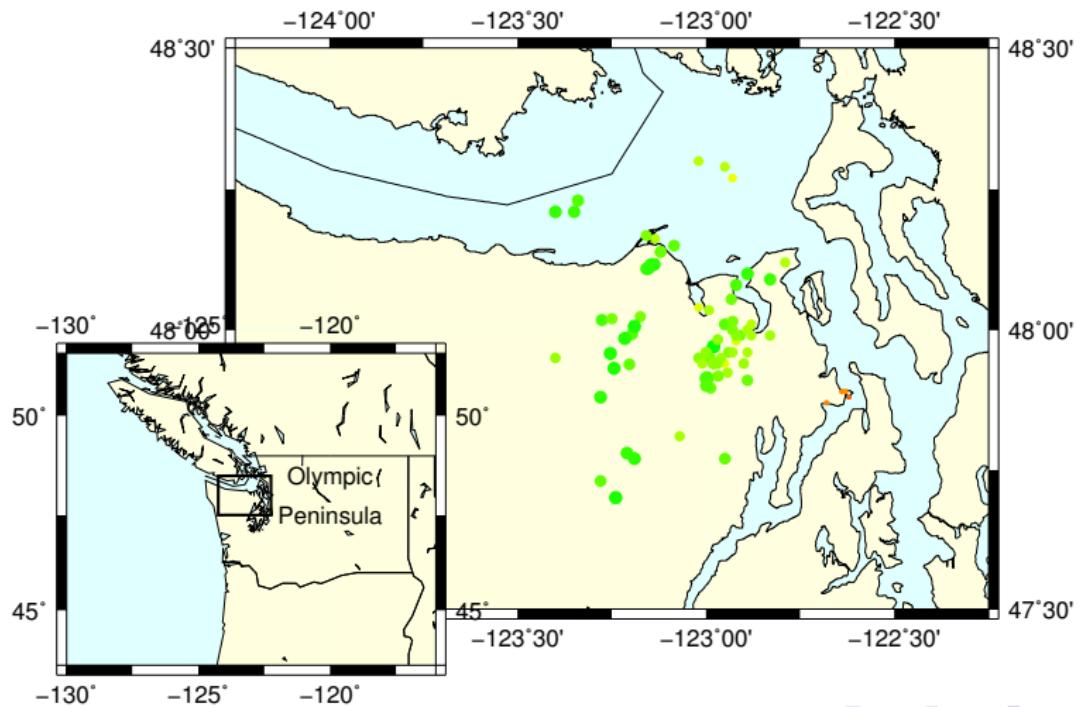

$m = \text{Sample size}$

V behaves as m^{2d-1}

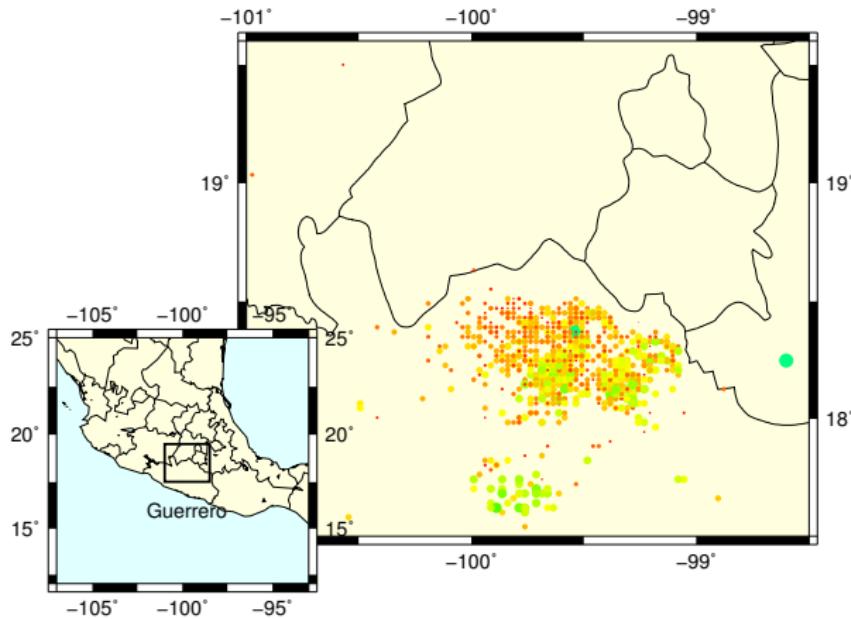

$$\rightarrow d = 0.117$$

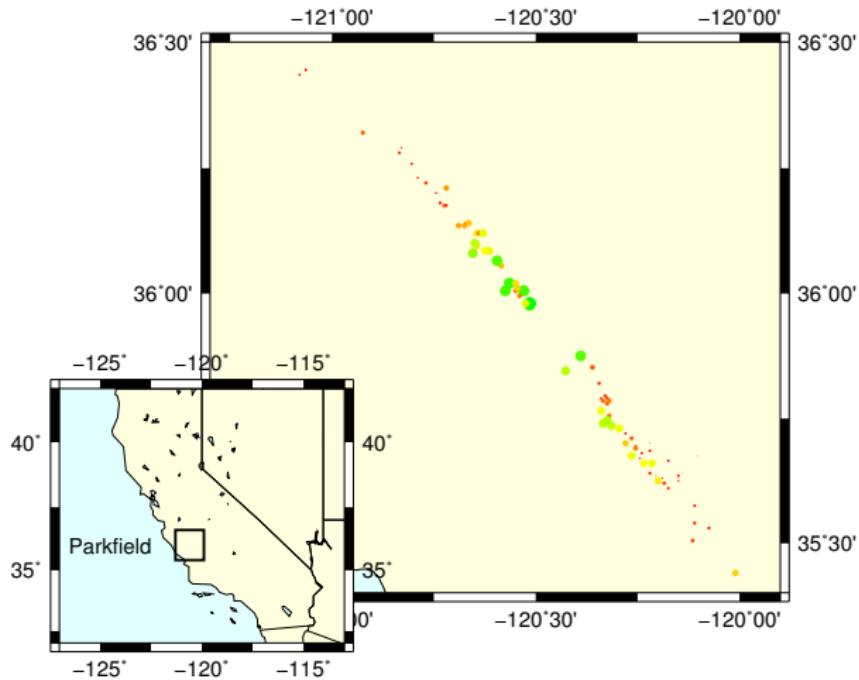

Northern Cascadia

Guerrero, Mexico

San Andreas Fault

Future work

- Computation of fractional index d for the southern Cascadia catalog
- Fit ETAS model on existing LFE families

Detection of slow slip events in New Zealand

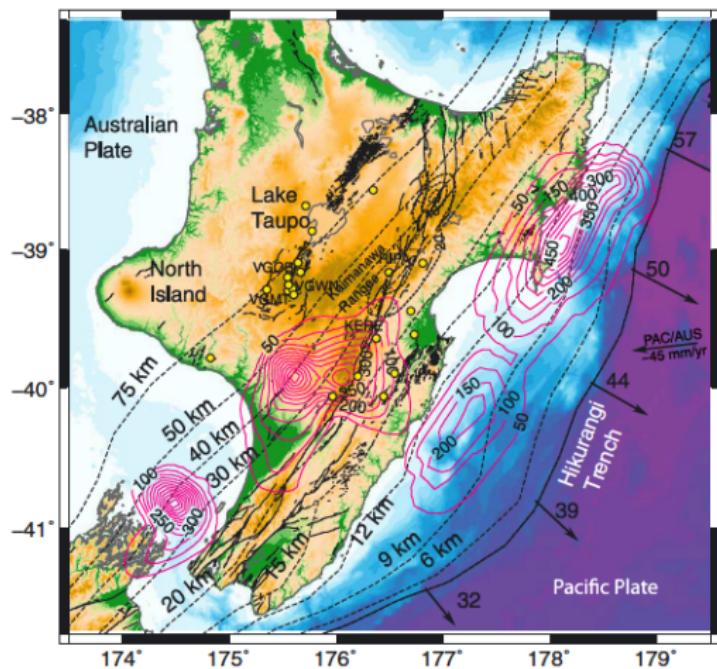

- 1 Introduction
- 2 Depth of the source of the tectonic tremor
- 3 A low-frequency earthquakes catalog for southern Cascadia
- 4 Detection of slow slip events in New Zealand
- 5 Time line

Tremor as proxy for slow slip

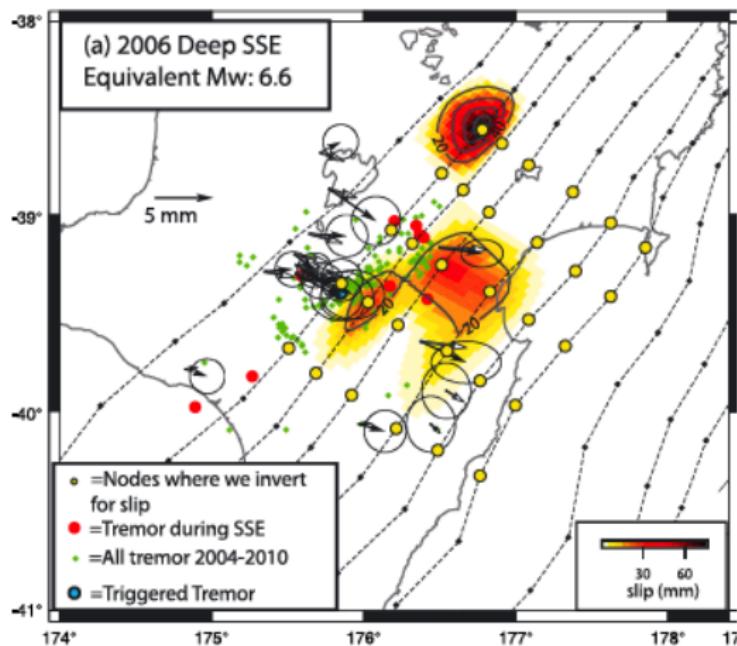

Episodic Tremor and Slip in Cascadia

- Tremor occurrence rate → Moment of slow slip events not detectable in the GPS data (Aguiar, 2009)
 - Stacking of GPS data when LFEs are detected (Frank, 2016)
- What do we do when tremor is not correlated with slow slip?

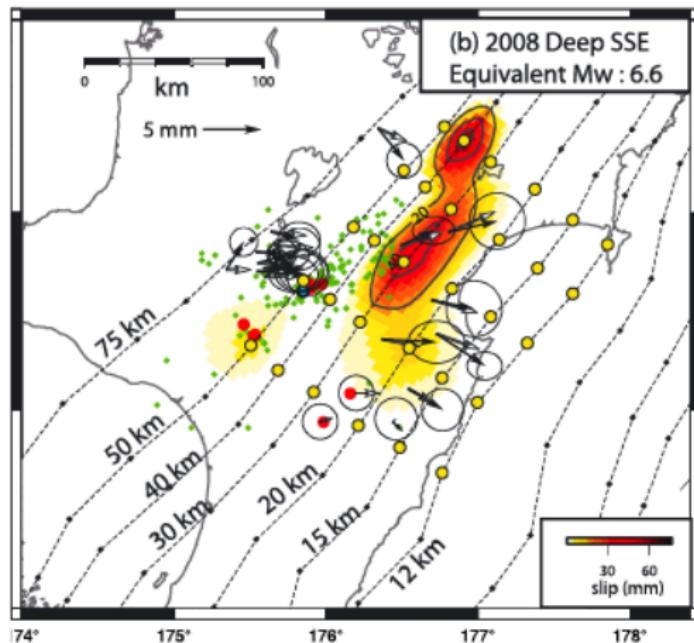

Northern New Zealand

Tremor during deep slow slip events

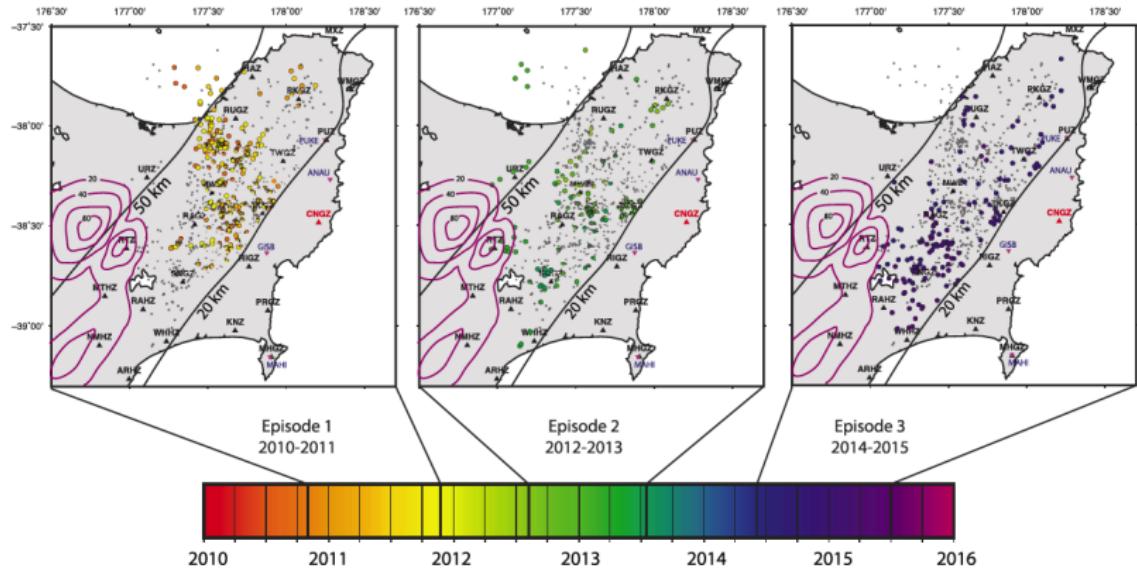

Tremor during deep slow slip events

Introduction

Depth of the source of the tectonic tremor
A low-frequency earthquakes catalog for southern Cascadia
Detection of slow slip events in New Zealand
Time line

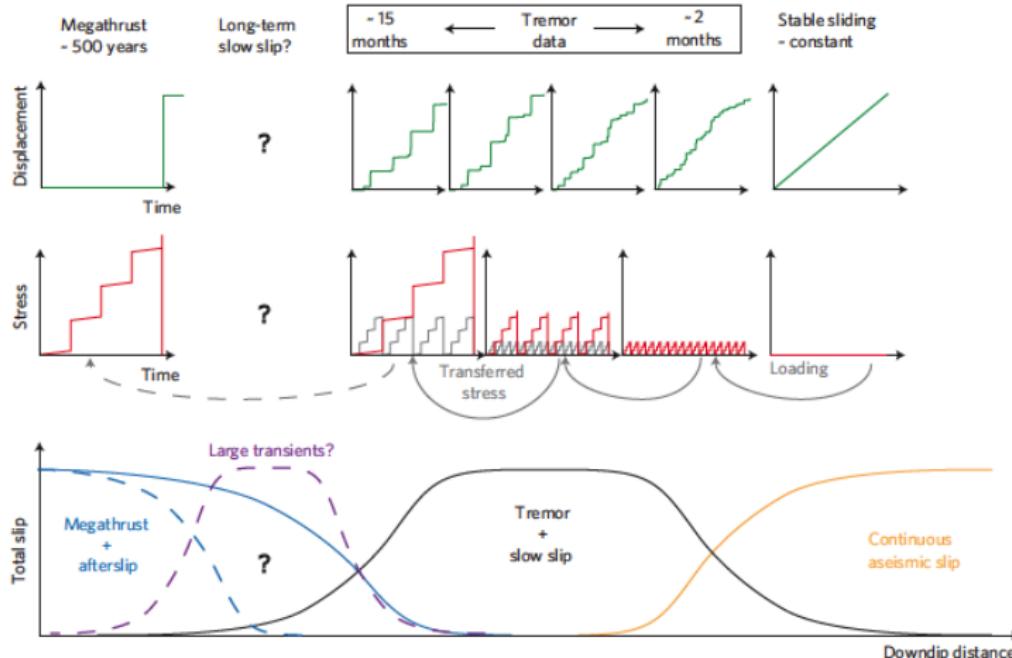

Tremor with no detected slow slip event

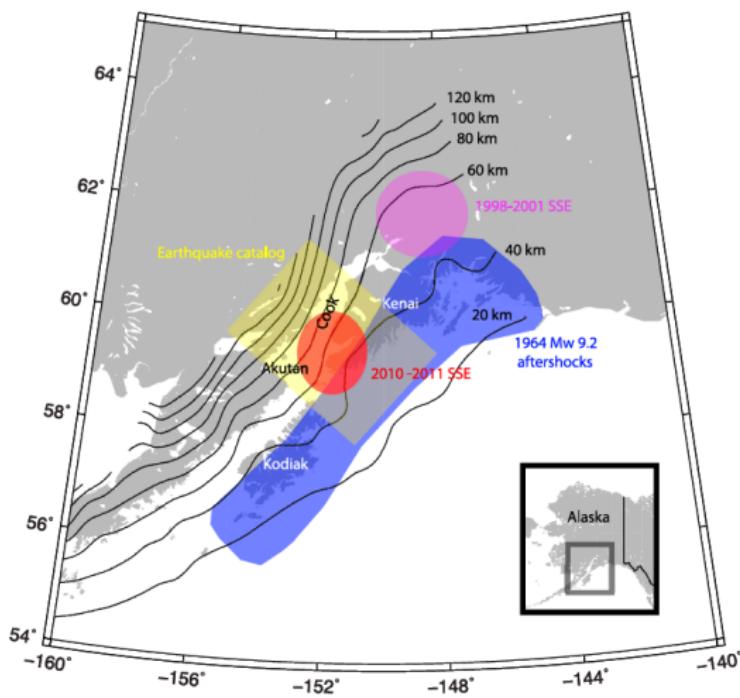

Possible questions

- Detecting smaller, currently undetected slow slip events
- Detecting longer term slow slip events
- Better measuring of the vertical displacement at the Earths surface during slow slip events

Detecting smaller, currently undetected slow slip events

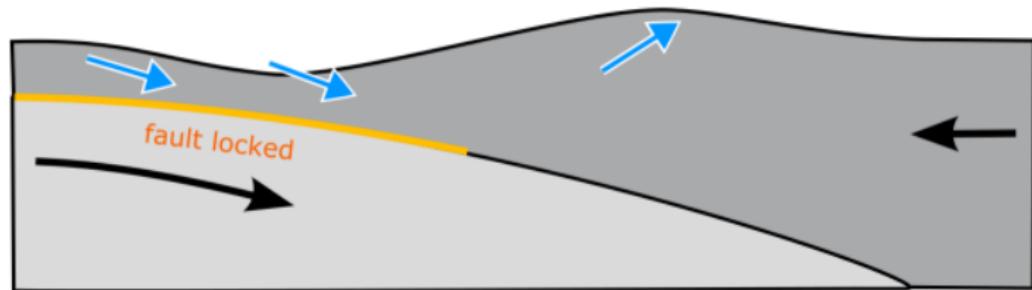

Detecting longer term slow slip events

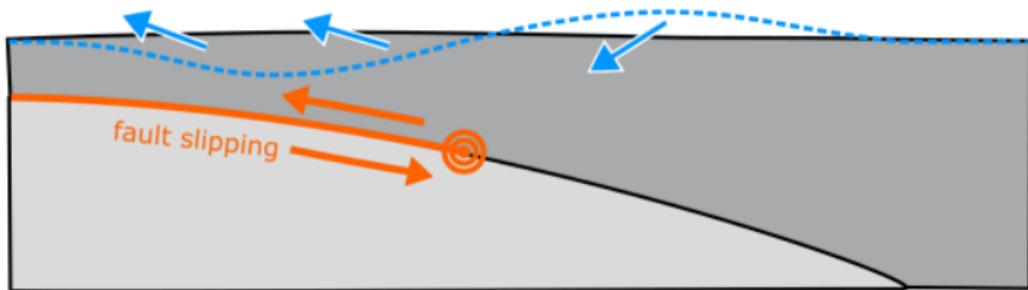

Better measuring of the vertical displacement at the Earths surface during slow slip events

LEVEL CHANGES BEFORE EARTHQUAKE

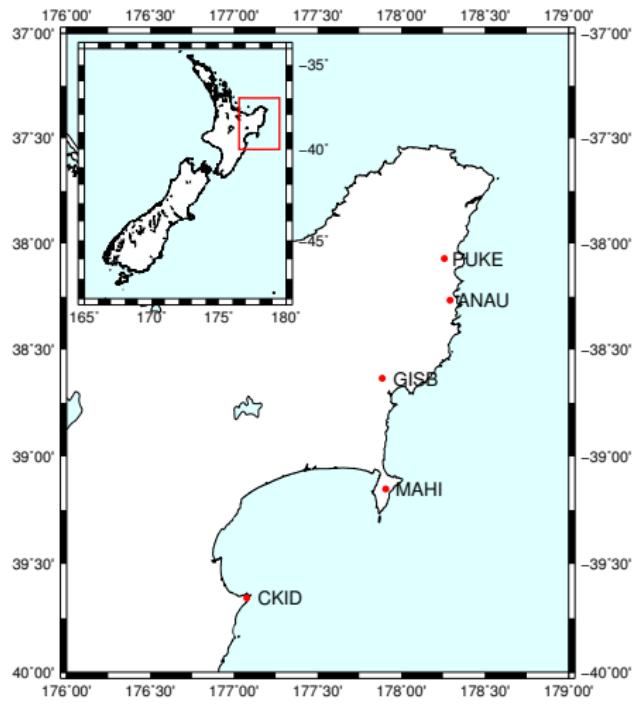

Better measuring of the vertical displacement at the Earths surface during slow slip events

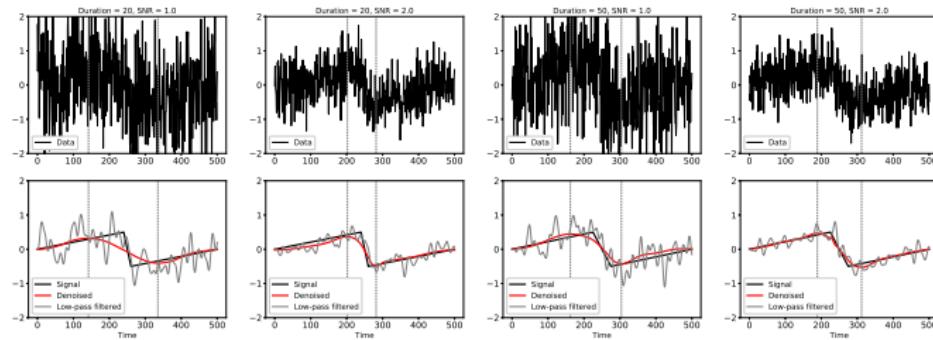

LEVEL CHANGES DUE TO EARTHQUAKE
